I. COMPUTATIONAL COMPLEXITY ANALYSIS

First, note that the computational complexity of the matrix multiplication for two matrices $M_{n \times m}$ and $M_{m \times p}$ is $O(nmp)$ using the definition of matrix multiplication, and of the matrix inverse for a matrix $M_{m \times m}$ is $O(m^3)$ using the Gauss–Jordan elimination method. (The results can be improved by advanced algorithms, e.g., the Strassen algorithm.) Therefore,

- 1) in the time-update step, the computational complexity of (18) is $O[(n+m) \times n + (n+m)]$, of (19) is $O[(n+m) \times n \times n + (n+m) \times n \times (n+m) + (n+m) \times (p+m) \times (n+m) + 2 \times (n+m) \times (n+m)]$;
- 2) in the step of obtaining the worst-case scenario, the computational complexity of (33) is $O[n+m]$, of (47) is $O[2 \times (n+m) \times (n+m)]$;
- 3) in the measurement-update step, the computational complexity of (35) is $O[n + m^3 + nmm + nm + n]$, of (36) is $O[n^2 + m^3 + nmm + nm + n^2]$.

Let $d := \max\{n, m, p\}$. As a result, the computational complexity of Algorithm 1 is asymptotically $O(d^3)$. Since for a usual state estimation problem, $n \geq p$ and $n \geq m$, the computational complexity of Algorithm 1 is $O(n^3)$.

II. SUPPLEMENTARY EXPERIMENTS

In Introduction I, we claim that the proposed method would be robust against uncertainties due to violation(s) of the following three types of assumptions.

- 4) μ_k^w, μ_k^v are exactly known and typically $\mu_k^w \equiv 0, \mu_k^v \equiv 0$;
- 5) Q_k and R_k are exactly known;
- 6) F_{k-1}, G_{k-1} , and H_k are exactly known.

In the experiment section (Section VI), we have studied the robustness of the proposed method against uncertainties in the system matrix F_k [i.e., the type 6)]. In this appendix, we investigate the robustness of the proposed method against uncertainties in the statistical properties, i.e., mean and covariance, of the noises, respectively. Comparisons are made with the non-robust canonical Kalman filter.

First, we suppose the mean vector μ_{k-1}^w of the process noise w_{k-1} is not exactly zero-valued [i.e., the type 4)]. In this case, the underlying true system is

$$\begin{cases} x_k = F_{k-1}x_{k-1} + \Gamma_{k-1}d_{k-1} + G_{k-1}w_{k-1}, \\ y_k = H_kx_k + v_k, \end{cases}$$

while the nominal system is

$$\begin{cases} x_k = F_{k-1}x_{k-1} + G_{k-1}w_{k-1}, \\ y_k = H_kx_k + v_k, \end{cases}$$

where we use $\Gamma_{k-1}d_{k-1} := G_{k-1}\mu_{k-1}^w$ to model the uncertain mean of w_{k-1} (strictly, the uncertain mean of $G_{k-1}w_{k-1}$). Without loss of generality, we still use the nominal values of $F_{k-1}, G_{k-1}, H_k, Q_{k-1}$, and R_k in Section VI. Besides, we assume $\Gamma_{k-1} := [1, 0]^T$ and d_{k-1} is a random variable which follows a standard Gaussian distribution. We have results in Fig. 1 (see also its caption for RMSEs),

Fig. 1. Results with $\gamma_2 = 1.005$, $\gamma_2 = 1.02$, and $\gamma_2 = 1.05$, respectively. RMSE: TMKF = 9.43, KF = 21.96, MKF (1.005) = 19.34, MKF (1.02) = 13.25, MKF (1.05) = 18.28.

through which the robustness of the proposed method against uncertainties in the mean of the noises is validated.

Second, we suppose the covariance matrices Q_{k-1} of the process noise w_{k-1} and R_k of the measurement noise v_k are not exactly known [i.e., the type 5)]. In this case, the underlying true system and the nominal system are

$$\begin{cases} x_k = F_{k-1}x_{k-1} + G_{k-1}w_{k-1}, \\ y_k = H_kx_k + v_k, \end{cases}$$

but they have different Q_{k-1} and R_k . We investigate a target tracking problem discussed in [1]. Therefore, the nominal values of $F_{k-1}, G_{k-1}, H_k, Q_{k-1}$, and R_k are:

$$F_{k-1} := \begin{bmatrix} 1 & \Delta t \\ 0 & 1 \end{bmatrix}, \quad G_{k-1} := \begin{bmatrix} (\Delta t)^2/2 \\ \Delta t \end{bmatrix}, \\ H_k := [1 \quad 0], \quad Q_{k-1} := 0.1, \quad R_k := 20^2,$$

where $\Delta t := 1$ (second) is the sampling time. The true values of Q_{k-1} and R_k are

$$Q_{k-1} := 0.1 + 0.1 \times q_{k-1}, \quad R_k := 20^2 + 10 \times r_k,$$

where q_{k-1} and r_k are two random variables following standard uniform distributions in $[0, 1]$. We have results in Fig. 2 (see also its caption for RMSEs), through which the robustness of the proposed method against uncertainties in the covariances of the noises is validated.

Fig. 2. Results with $\gamma_2 = 1.005$, $\gamma_2 = 1.02$, and $\gamma_2 = 1.05$, respectively. RMSE: TMKF = 10.16, KF = 12.65, MKF (1.005) = 12.43, MKF (1.02) = 11.88, MKF (1.05) = 489.86.
